TITLE: Dependence of spontaneous voltage oscillations of a glow discharge in oxygen on the length of positive column

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika, no. 9, 1962, 50, abstract 9Zh299 (Studii si cercetări științ. Acad. RPR Fil. Iasi. Fiz. si științe tehn. v. 11, no. 2, 1960, 183-188 (Rum.; summaries in Fr. and Rus.))

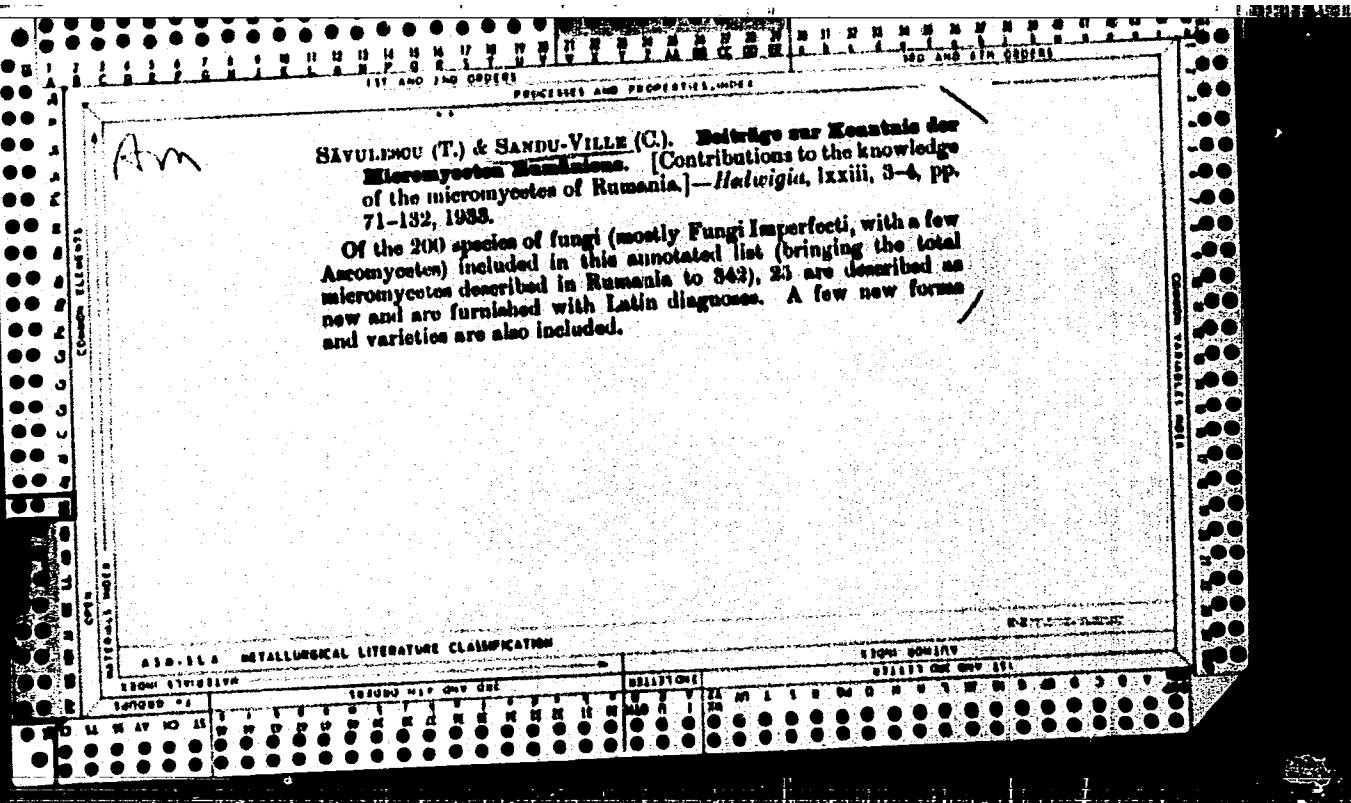

TEXT: In glow discharges with anomalous potential drop at the cathode, when the anode is situated in the positive column, the frequency of voltage oscillations depends inversely on the length of the column. These oscillations can be considered as self-resonant oscillations of the positive column which constitutes a linear oscillator. It follows that oscillations with a determined self-resonant frequency can exist not only in the discharge column

*turcicum* [ibid., xiv, p. 685], first recorded in Rumania in 1933, caused severe infection of maize in several localities and also occurred on sorghum near Bucarest. Foot rot of barley was caused by *F. culmorum* [ibid., xiii, p. 623].

Attention is drawn to the important part played by self-sown plants in the dissemination of most of the above-mentioned fungi, which live over on volunteer plants until the winter cereal crops appear. Cereal rust spores fall on the ground before and during harvest, remain alive on the stubble, and pass on to self-sown plants, where they produce new spores which in turn infect the young winter wheat. The severity of the autumn infection of cereal rusts depends on the date of sowing and the meteorological conditions, and owing to favourable weather in the autumn of 1934, severe infection was general throughout Rumania. *Leptosphaeria tritici* [ibid., viii, p. 290] is transmitted to wheat in autumn from self-sown plants, as is *L. passerinii* to barley; both cause a yellow discoloration of the leaves. *Erysiphe graminis*, commonly present on wheat and barley leaves, spreads during summer from self-sown plants to autumn crops.

TITLE: Photosensitivity of thin semiconductive layers

SOURCE: Zhurnal nauchnoy i prikladnoy fotografii i kinematografii, v. 10, no. 6,  
1965, 450-451

TOPIC TAGS: photosensitivity, visible light, semiconducting material

ABSTRACT: CuCl was found to have the same photosensitivity properties as are exhibited by PbI<sub>2</sub>. When deposited in thin layers on quartz or glass, these compounds form latent images upon exposure to visible light. These images may be developed on heating. Temperatures required are 180-240°C for PbI<sub>2</sub> and 150-200°C for CuCl. If heated to these temperatures during exposure, the latent images appear on subsequent exposure to radioactivity. The source of light may also serve as the source of heat in developing the latent image. It was shown that other halides are also light sensitive. Compounds of sulfur (As<sub>2</sub>S<sub>3</sub>, Sb<sub>2</sub>S<sub>3</sub>, CdS, PbS), selena (As<sub>2</sub>Se<sub>3</sub>) and

Card 1/2

UDC: 772.93.01

L 13871-66  
ACC NR: AP5028146

tellurite (ZnTe) are similarly photosensitive. Light sensitive layers are produced by vacuum deposition at pressures on the order of  $10^{-4}$ - $10^{-5}$  cm Hg. The layers are exposed for a period of from a few minutes to an hour. They are then heated in an oven for from 5-10 minutes, at temperatures between 100°C and 200°C. The reaction apparently takes place as a result of the rupture of the electronic bonds of CuCl. The cuprous and chloride ions react in pairs in the defects of the crystal lattice and form molecules of chlorine and copper. The atoms of copper are trapped in the lattice forming the resultant visible image. Heating accelerates the rupture of the bonds of CuCl. By selecting appropriate semiconductive material, layers can be produced which are sensitive to various portions of the spectrum. Applications may be found in microphotography. TITLE: Radar Observations of the Polar Lights at Mirnyy

PERIODICAL: Inform. byul. Sov. antarkt. ekspeditsii, 1959, No. 13, pp. 29-33

TEXT: The radar observations of polar lights began at Mirnyy in 1959. A radar with revolving antenna is used which operates at 72 Mc frequency; the coverage of the radar is 1,000 km. Altogether 7,333 shots were taken during the observation period; 585 of them were with reflections. The reflections represent in the overwhelming majority of the cases a totality of individual pulses which are not resolved with respect to the distance. The auroras were observed in the main from 4<sup>h</sup> to 20<sup>h</sup> Greenwich Time; two maxima in 5<sup>h</sup> - 8<sup>h</sup> and 12<sup>h</sup> - 16<sup>h</sup> are expressed clearly. In March, the reflection rose is presented by a three-lobe configuration, the main lobe of which is directed to East; in April, the main

lobe has 40° azimuth. In May, a nearly uniform distribution of the reflections was observed in the sector from 30° - 90°. Reflections from distances of 650-750 km occurred most frequently. The altitude values obtained were less than 100 km.

TITLE: Radar observations of auroras at Soviet Antarctic stations in 1959

PERIODICAL: Geomagnetizm i aeronomiya, v. 1, no. 5, 1961, 679 - 686

TEXT: The authors analyze the results of radar observations of auroras carried out at the Mirnyy and Vostok stations in 1959. Peculiarities in the seasonal variations of the number of reflections at Mirnyy are noted. In the diurnal rate two maxima were observed, which are created by reflections received from various directions. They are probably connected with the basic and inner zones of auroras. Similar conclusions can be drawn from data obtained from the Dumont-Durville station. The diurnal rate of the number, the azimuth, and the distance of reflections is illustrated in a number of graphs. At the Vostok station, the diurnal variation is characterized by a minimum with almost complete absence of reflection during the morning hours (local time 0 - 5 hours UT). During the day the number of reflections increases sharply, attaining a maximum in the afternoon and early evening (8 - 10 hours UT); and then decreasing. The radar observations carried out at Mirnyy and Vostok during a relatively short period revealed a num-

Card 1/2

S/203/61/001/005/009/028

A006/A101

Radar observations ...

ber of substantial peculiarities in the geophysical phenomena of these regions. Two types of reflections are detected, the one of which should be connected with the basic zone of auroras and the other one with the inner zone. This statement does not only support the hypothesis on the existence of an inner zone, but reveals also some of its properties, such as activity during the day. This fact proves the efficiency of employing radar methods for geophysical investigations, which should be preferably used when investigating the second zone. Another peculiarity is the absence of correlations between radar reflections and magnetic activity, characteristic of intrazonal stations (e.g. Mirnyy). The observations are continuing. There are 9 figures and 5 references: 4 Soviet-bloc and 1 non-Soviét-bloc.

Title : Natural Frequencies of a Compressed Nucleus in the Non-Static Statistical Model

Orig Pub : Studii si cercetari fiz. Acad. RPR, 1957, 8, No 4, 433-444

Abstract : The non-static consideration in the statistical model, developed first by Bloch (Bloch, F.Z., Phys. 1933, 81, 363) and supplemented by Jensen (Jensen, H.Z., Phys. 1937, 106, 620) for the atom, is extended to include a compressible nucleus. Only such excitations are investigated, which do not produce thermal motion in the nucleus, and which to an ordered hydrodynamic motion. The change in density in the nuclear liquid arising in this case is considered as a small perturbation. The equation for the perturbation in the density is derived from the least-action principle under the condition that the ratio of the number of neutrons to the number of protons in

ORIG. PUB.	: Studii si Cercetari Chim Acad RPR, 6, No 4, 527-538 (1958)	
ABSTRACT	The effect of catalyst concentration (0.25-0.5%), temperature, degree of conversion, and air flow rate on the rate of absorption of O <sub>2</sub> during the oxidation of cyclohexane by air in the liquid phase has been investigated. The activation energy for the reaction in the presence of Co naphthenate has been determined and found to be 19.5 kcal/mol. It is shown that the length of the chain is nearly independent of the temperature. From authors' summary

Liquid-phase oxidation of cyclohexane with air. Lucinda Birdleman, C. D. Coates, and T. Sindulescu. J. Am. Chem. Soc., 72, 2202 (1950). Cyclohexane ( $\eta = 0.77^{\circ}$ ,  $\rho = 0.794$ ,  $n_D^{20} = 1.4235$ ) (I) was oxidized under various flows of air at 135-65°/5 atm. in the presence of 0.1-2.0% concn. of Co naphthenate (5% metallic Co) as catalyst to det. the best conditions under which the rate of O absorption reached its max. The reaction took place in an electrically heated tubular steel reactor equipped with a cooling sleeve at the top and a compressor as the source of air. The evolved gas passed through a series of tubes filled with C, which retained I, and then on to an Orsat app. for the gas analysis. In the 600-cc. reactor the I liquid phase almost completely occupied the reaction space so that practically no vapor space existed at the reaction temp. CO<sub>2</sub> and O were detd. in the evolved gas at intervals varying between 15 and 30 min., and the total amt. of absorbed O and its absorption rate calc'd. at any given moment. The product was distilled from the aq. layer, then dried, to eliminate the unreacted I, and the oxidation product cyclohexanol (II) was detd. by acetylation with AgO in pyridine. Cyclohexanone (III) by

the gravimetric method based on condensation with furfural. The free acids by the index of acidity, and the esters by the index of esterification. The II + III content could be quite accurately detd. by scrpt. The 185-64° distn. fraction which, being contaminated with acids and esters, indicated the necessity of submitting the oxidation product to an alk. hydrolysis, followed by vapor trailing, thus obtaining a II-III fraction of higher purity and increasing the yield by 2-4%. It was found that the O absorption was max. at 145° with 0.25-0.50% catalyst and a conversion of approx. 12%, yielding a II-III fraction of 60-65% after 80-90 min. of reaction time. The oxidation reaction of I in the liquid phase is an autocatalytic homogeneous reaction due to a practically const. rate of O absorption. The activation energy of I oxidation in the presence of Co naphthenate is 19,000 cal./mol.<sup>1</sup>. Temp. has very little effect on the duration of the chain reaction, if any at all. It was shown that the speed of global oxidation can be expressed by an equation based on the general theory of liquid-phase oxidation of I using for its deduction a reduced no. of elementary reactions.

TITLE: The Study of Catalysts by Gas Chromatography.  
Part I. Chromatographic Characteristics of Oxide  
Catalysts for the Polymerization of Olefins

PERIODICAL: Revista de Chimie, 1960, Vol 11, Nr 3, pp 151-155

ABSTRACT: The authors describe their studies on the chromatographic behavior of silicon-alumina basis and catalysts of ethylene polymerization. The work carried out by the authors included the study of chromatographic characteristics, the volume of retention and the elution peak. It was established that ethylene and propylene are chemically absorbable by the basis even with temperatures ranging from 0° to 100°C. The authors also explain the influence of chromium oxide on the activities of the catalyst and interpret the influence of the activating tem-

perature. They show that the important process in polymerization is the surface mobility of the carbon ion and not its formation. The article shows the preliminary data obtained by studying catalysts of silicon-alumina with chromium oxide by applying gas chromatography. The work represents an experiment to establish new evaluation methods, clarifying also the action of the catalyst. Many treatises on the catalysts activities, especially their acid properties, dealt with these problems, such as the works by Lewis and Brönsted. A complete study was contributed by Miesserov [Ref 2, 3] whereas a comparison between the different types of catalysts can be found in the works by Frost [Ref 4] and Handford [Ref 5]. Recently it was made clear that the most active regions

The Study of Catalysts by Gas Chromatography. Part I. Chromato-graphic Characteristics of Oxide Catalysts for the Polymerization of Olefins

of the silicon-alumina catalysts correspond to a great extent to Lewis acids. It is evident that in these reactions the basis intervenes directly, due to the potential function of Lewis acids to form carbon ions, necessary in polymerization (according to Whitmore), but the influence of chemical compositions and other factors is not yet sufficiently known. A recent work [Ref 8] shows the parallel between the surface acidity of the catalyst and the conversion of propylene in the polymerization reaction. In another recent work [Ref 9] the magnetic properties of the chromium-silicon-alumina oxide system are studied for the purpose of defining the catalytic action by using the oxidation number and the distributing of chromium on the basis; it is shown that the basis has a strong influence upon the oxidation phase of chromium during activation.

D0016/D3001

The Study of Catalysts by Gas Chromatography. Part I. Chromato-graphic Characteristics of Oxide Catalysts for the Polymerization of Olefins

The authors tested the silicon-alumina basis and catalysts with chromium oxide activated at 500 to 600°C. Granulation was 0.15 to 0.4 mm. Ethylene and propylene manufactured by ICECHIM had an impurity content of less than 0.5%. Prior to the determination, the sample was tried by passing a hydrogen current at 120-150°C for one hour. The "T<sub>1</sub>" and "T<sub>2</sub>" translators, which are part of the chromatographic installation in the gas phase (Figure 1) build a derivation of a Wheatstone bridge. The second derivation is made of a potentiometric wire belonging to a Heyrovsky micro-polarograph. Figure 2 shows that in the case of ethylene, the introduction of chromium

and the activation at 500°C and 600°C does not es-sentially modify the retention volume and its varia-tion of temperature. Results obtained by the authors are in conformity with the observations by Clark [Ref 14]. The authors also agree with Millinken [Ref 16] in their criticism of the evalua-tion method of the catalytic activity by acidity titra-tion. AUTHOR: Sandulescu, D.

TITLE: Experimental gas chromatography. V. Fixed phase

PERIODICAL: Revista de Chimie, no. 6, 1961, 341 - 345

TEXT: The author describes the principles of gas chromatography and presents some general considerations on the action and selection criteria of the fixed phase in gas-solid (GSC) and gas-liquid (GLC) chromatography. For some years, columns with the liquid distributed directly on the column without any support have been used more frequently. The main active supports are activated coal, silica gel, alumina and molecular sieves. The size of the granules ranges from 0.1 - 0.4 mm and the material is degassed at 120 - 200°C. Activated coal is used particularly for the adsorption of H<sub>2</sub>, O<sub>2</sub>, N<sub>2</sub>, CO and CH<sub>4</sub>, whereas silica gel may be used for the analysis of ethylene and the usual impurities. The tailing of the elution peaks in GSC can be considerably reduced by using a particular liquid, e.g. dioctyl-phthalate for silica gel and "scalan", deposited from a solution in petroleum ether, for active coal. /Abstracter's note:

Card 1/4

R/003/61/012/006/001/001  
D019/D105

Experimental gas chromatography. V. Fixed phase

"scalan" could not be found in available reference material<sup>7</sup>. Considerable progress has been achieved with the use of molecular sieves: in some cases the selectivity of the adsorption is very high, attaining the separation of the activated optical isomers, as described by V. Vîntu and D. Săndulescu in Analele Româno-Sovietice, 3, 1960, p 99. Molecular sieves may be used especially in the analysis of gases which do not easily liquefy, since they permit a good separation of O<sub>2</sub>, N<sub>2</sub> and CO. The supports used in GLC are diatomites and silicon firebricks. Diatomites are known as "celite 535", "celite 545", and "chromosorb". Rumanian diatomites suitably prepared may also be used. The material is suspended in water in an 18-cm-high beaker, in a 1 : 20 proportion, and the precipitate formed within 3 minutes dried, calcined for three hours at 300°C, then rinsed first with hydrochloric acid, then with water and finally dried. Treatment with a 5% solution of sodium hydroxide in methanol is often recommended. Sodium chloride, teflon granules, small glass beads, firebrick with silver-coated granules, sand, quartz and carborundum can also be used in

Card 2/4

R/003/61/012/006/001/001  
D019/D105

Experimental gas chromatography. V. Fixed phase

many analyses. To obtain a high column efficiency a granule size of 0.02 - 0.06 mm, in case of diatomites, and 0.1 - 0.6 mm in case of other material is recommended. The eventual adsorption activity of the support may be determined by impregnating the support with different quantities of liquid and by calculating the specific degree of retention, which must be constant regardless of the support loading. A relatively high activity of the support may also be determined by the presence of tailings at the elution peaks. The optimum operation of an installation depends on the optimum quantity of liquid distributed: a liquid quantity of 15 - 20% is recommended but in a few cases good results were obtained with a liquid quantity of 1 - 5%. In case of materials of low porosity, such as sodium chloride, the liquid quantity is maximum 3 - 5%. One of the most difficult problems of gas chromatography is the loss of liquid, which can, however, be reduced by using a small quantity of liquid, i.e. less than 10% on the support. A column of good stability should not have a loss higher than 1 mg/hr; in many cases, however, a loss of 1 g/min is allowed. In case of

D019/D105

Experimental gas chromatography. V. Fixed phase

volatile liquids, a saturation vessel is placed before the column and a part of the dry support after the column, which prevents the liquid from reaching the detector. A column will keep its initial efficiency in 100 analyses, provided uninterrupted operation of the apparatus is maintained. There are 6 figures and 3 tables.

TITLE: High-purity alumina for catalysts

SOURCE: Revista de chimie, v. 15, no. 11, 1964, 665-667

TOPIC TAGS: catalysis, industrial catalyst, alumina

ABSTRACT: [Authors' English summary modified]: The authors describe the preparation of high-purity alumina by using aluminum isopropoxide as an intermediate. The raw materials used are aluminum, isopropyl alcohol, and very small quantities of carbon tetrachloride and mercurous chloride, and the technological scheme is quite simple and economical.
